Log-normal model

In this section, we include the results of the same cumulative models presented in the main paper, but using a log transformation of reaction times. We decided to present raw reaction times in the main text to improve the interpretability of the model parameters, particularly the variance decomposition.

By-subject cumulative effect

We also computed a by-subject cumulative effect by applying the same model separately to each participant. Clearly, we only have the estimation of β_0 , β_1 and σ_E .
